Cell Reports

Saturated fatty acids dampen the immunogenicity of cancer by suppressing STING

Graphical abstract

Highlights

- Obesity establishes an IFN-I-deprived tumor microenvironment and increases tumor burden
- Myeloid cells from obese hosts are desensitized to STING stimulation
- Saturated fatty acids inhibit the STING pathway by inducing NLRC3
- NLRC3 inhibits the immunogenicity of HNSCC in an IFN-Idependent fashion

In brief

The STING-type-I interferon pathway underpins immune surveillance against cancers. However, how metabolic comorbidity contributes to STING suppression is unclear. Heath et al. find that myeloid cells from obese hosts are desensitized to STING. Saturated fatty acids can inhibit STING by inducing NLRC3, dampening the immunogenicity of cancers.

SUMMARY

Oncogenes destabilize STING in epithelial cell-derived cancer cells, such as head and neck squamous cell carcinomas (HNSCCs), to promote immune escape. Despite the abundance of tumor-infiltrating myeloid cells, HNSCC presents notable resistance to STING stimulation. Here, we show how saturated fatty acids in the microenvironment dampen tumor response to STING stimulation. Using single-cell analysis, we found that obesity creates an IFN-I-deprived tumor microenvironment with a massive expansion of suppressive myeloid cell clusters and contraction of effector T cells. Saturated fatty acids, but not unsaturated fatty acids, potently inhibit the STING-IFN-I pathway in HNSCC cells. Myeloid cells from obese mice show dampened responses to STING stimulation and are more suppressive of T cell activation. In agreement, obese hosts exhibited increased tumor burden and lower responsiveness to STING agonist. As a mechanism, saturated fatty acids induce the expression of *NLRC3*, depletion of which results in a T cell inflamed tumor microenvironment and IFN-I-dependent tumor control.

INTRODUCTION

Immune checkpoint blockade (ICB) has recently become the first-line treatment for multiple types of solid tumors, including head and neck squamous cell carcinomas (HNSCCs). In contrast to the decline of overall cancer incidence in the United States, the cancer burden of HNSCC continues to increase and will maintain an upward trend until the year 2060.^{1,2} This is largely driven by the prevalence of human papillomavirus (HPV)-associated oropharyngeal squamous cell carcinomas (OPSCC). OPSCCs have very high mutational burdens and frequently contain HPV16 viral epitopes, which cannot evade immune detection through central immune tolerance. However, its response to ICB is usually below 15%.^{3,4} This clinical observation suggests that the immunogenicity of OPSCC is controlled

by mechanisms beyond the presence of immunogenic epitopes. Understanding the mechanisms underpinning cancer immunogenicity is pivotal to developing strategies to sensitize hypoimmunogenic cancers to immune killing.

Recently, we found that cancer cell-specific expression of an adaptor molecule for type-I interferon (IFN-I) activation, stimulator of interferon genes (STING), is a strong positive prognosticator in HNSCC patients.⁵ In addition, when HNSCC cells became resistant to effector immune cell-mediated killing, multiple inhibitors of the STING-IFN-I pathway were upregulated in cancer cells.⁶ Indeed, the proper activation of IFN-I is essential for the expression of MHC Class I molecules and antigen presentation.^{7,8} These findings suggest that the fitness of STING-mediated innate immune surveillance in the HNSCC tumor microenvironment (TME) is essential for the detection and control of cancers.

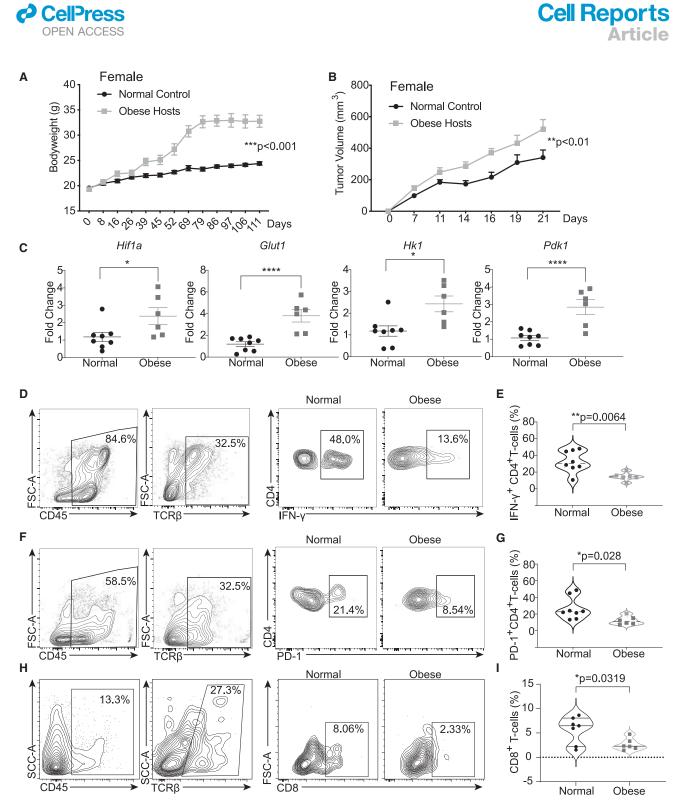

Figure 1. Obesity exacerbates intra-tumoral hypoxic stress and inhibits effector T cell function

(A) To establish the obesity model, six-week-old female C57BL/6 mice were fed either a normal (11.4% kcal fat) or high-fat (60% kcal fat) diet for twelve weeks prior to tumor implantation and monitored for weight for the duration of the experiment (n = 16 normal-weight and n = 14 obese mice). Bodyweight differences between groups were assessed using the generalized estimating equation model (***p < 0.001).

(B) One million MOC2-E6/E7 cancer cells were implanted subcutaneously into the right flank of normal-weight and obese mice and monitored for tumor growth (n = 16 normal-weight and n = 14 obese mice). Tumors were measured every 2–4 days. Tumor burden between groups was compared using the generalized estimating equation model (**p < 0.01). Obesity *in vivo* experiments were performed twice (n = 24 normal-weight and n = 20 obese mice).

Priming strategies that aim to reinvigorate innate immune sensing are being extensively tested in preclinical models, and many have advanced into phase 1/2 clinical trials to sensitize hypoimmunogenic cancers to ICB. For example, radiotherapy has recently emerged as a promising priming treatment modality for HNSCC.^{9–11} Notably, the success of radiotherapy depends on intact STING signaling with defects in the STING pathway dampening radiotherapy-induced sensitization to immune killing.^{12,13} HNSCC resistance to the combination of radiotherapy and immunotherapy has been an emerging pivotal challenge.¹⁴ Thus, it is important to identify mechanisms that lead to STING insufficiency in HNSCC.

Driver oncogenes frequently keep STING activation in check to facilitate immune escape. For example, HPV16 E7 can facilitate the protein turnover of STING by engaging NLRX1-dependent autophagosomes.⁵ As an independent oncogenic event, in about 20% of HNSCCs, the amplification of the 3q26.3 genetic locus is present with the co-amplification of SOX2 and PIK3CA. Similar to HPV16 E7, SOX2 can also destabilize STING through autophagy-dependent machinery.⁶ The consequent IFN-Ideprived tumors show features of hypoimmunogenicity, such as resistance to ICB and decreased diversity of T cell receptors.¹⁵ Thus, the identification of key checkpoints of STING is critical to understanding the HNSCC adaptive resistance to innate immune priming. In addition, intra-HNSCC myeloid cells are typically devoid of epithelial oncogenes, and the mechanisms shaping their response plasticity to STING stimulation remain insufficiently characterized.

Metabolic dysregulation has recently emerged as a major underlying condition affecting HNSCC incidence and response to therapies. The link between obesity and the risks for several types of gastrointestinal tract, breast, esophageal, and endometrial cancers has been extensively studied; however, the impact of obesity on HNSCC was not well characterized until recently. Evidence from several large independent cohorts in different continents suggests that obesity is a previously underappreciated risk factor for HNSCC. In the NIH-AARP diet and health prospective cohort involving 218,854 participants and a Spain prospective cohort involving 3.5 million adults, obesity was a significant risk factor for HNSCC.^{16,17} A similar finding was made in a cohort involving about 6.7 million patients in South Korea.¹⁸ Among patients who were positive for HPV, the risk of OPSCC was increased with higher body mass index values.¹⁹ HNSCC patients, especially the HPV⁺ OPSCC population, who took statins to reduce cholesterol levels showed improved clinical outcomes.^{20,21} Overall, these findings suggest that obesity is a significant risk factor for HNSCC initiation and escape from the immune system.

In this study, we aimed to characterize the molecular mechanism underpinning obesity-potentiated immune escape of

HNSCC. We mapped the anti-tumor immune response in obese hosts at single-cell resolution and found that obese hosts establish an IFN-I-deprived tumor microenvironment with significantly increased HNSCC burden. We and others have shown that STING agonists exhibit potent therapeutic potential for HNSCC.^{6,8,22-24} However, STING agonists lost effectiveness in obese tumor-bearing hosts. Bone-marrow-derived macrophages (BMDMs) and peritoneal macrophages from obese mice were insensitive to STING stimulation. In agreement, the myeloid-derived suppressor cells (MDSC) derived from bone marrow and those from the TME in obese hosts were more suppressive of effector T cell activation. We found that saturated fatty acids, but not unsaturated fatty acids, inhibited IFN-I signaling through the upregulation of NLRC3, a recently identified DNA-binding protein that suppresses the STING pathway. We further showed that NLRC3 sensed saturated fatty acids and inhibited HNSCC immunogenicity in an IFN-I signalingdependent fashion. Overall, this study describes a molecular link between obesity and cancer cell escape from innate immune sensors and identifies a central metabolic pathway that controls HNSCC immunogenicity.

RESULTS

Obesity exacerbates intra-tumoral hypoxic stress and inhibits effector T cell function

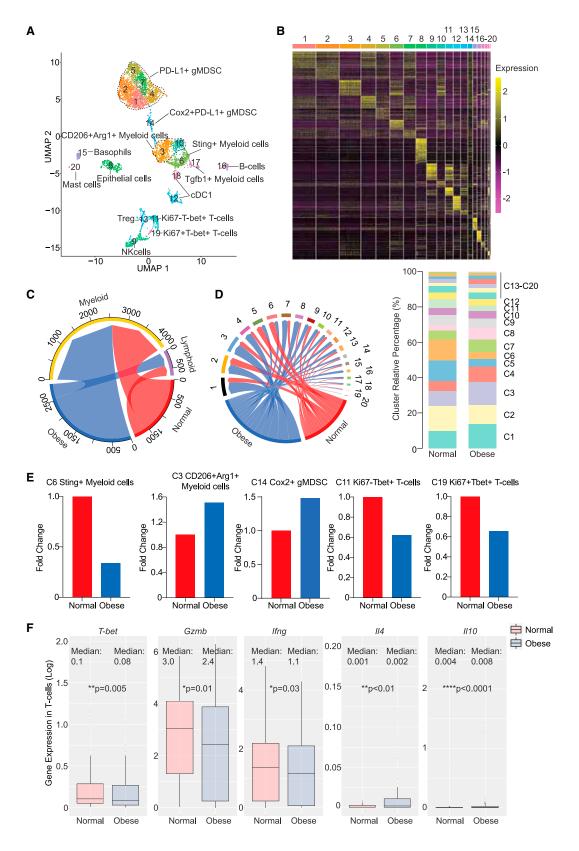

To understand the effects of obesity on tumor burden and the TME, we first established an obese mouse model by feeding four- to six-week-old C57BL/6 female mice either a normal chow diet (consisting of 11.4% kcal fat content) or a 60% kcal high-fat diet for twelve weeks,²⁵ and monitored mouse weights weekly (Figure 1A). After twelve weeks, we used the MOC2-E6/ E7 syngeneic HNSCC tumor model, which does not respond to ICB monotherapies.^{5,6} One million MOC2-E6/E7 cells were implanted subcutaneously into the right flank of mice fed either normal chow or a high-fat diet and monitored for tumor burden starting one week following implantation. We found that obese mice displayed a significantly higher tumor burden in relation to normal control mice (Figure 1B). Hypoxia is a key feature of the HNSCC TME, which shows a median partial pressure of oxygen (pO₂) of 9 mm Hg, in contrast with a pO₂ of 40–60 mm Hg in the paired normal tissue.²⁶ Hypoxia drives autophagy to switch the dominant metabolism from oxidative phosphorylation to glycolysis.²⁷⁻³⁰ We resected tumors from control and obese hosts and homogenized tissue for qPCR analysis of the glycolysis pathway markers. We found the tumors from obese mice displayed even higher levels of Hif1a, Glut1, Hk1, and Pdk1 (Figure 1C). It has been previously shown that effector T cell function requires sufficient extracellular glucose support to sustain rapid

⁽C) Total RNA was isolated from one representative set of whole excised tumors. The transcripts of the glycolysis pathway intermediates *Glut1*, *Hk1*, *Pdk1*, and *Hif1a* were quantified via qPCR (n = 8 normal-weight mice; n = 6 obese mice). Values represent mean \pm SEM of three technical replicates per tumor. All comparisons between two groups were made using a two-tailed unpaired *t* test (*p < 0.05 and ****p < 0.0001).

⁽D-G) Tumor-infiltrating lymphocytes from one representative set of experiments were analyzed by flow cytometry. The gating strategy was as follows: lymphocytes, singlets, live cells (Zombie Aqua negative), CD45⁺, TCR β^+ , and CD4⁺. The frequencies of IFN γ^+ CD4⁺ and PD-1⁺CD4⁺ T cells were analyzed by flow cytometry (n = 8 normal-weight mice; n = 6 obese mice). All comparisons between two groups were made using a two-tailed unpaired *t* test (**p < 0.01). (H and I) Tumor-infiltrating CD8⁺ T cells were analyzed using flow cytometry (n = 7 lean mice; n = 6 obese mice). Comparisons between the two groups were made using a two-tailed unpaired *t* test (**p < 0.01).

(legend on next page)

genome replication, cytokine synthesis, and cytotoxic cargo delivery, and that a lack of metabolic support results in T cell exhaustion.^{31–35} As the tumors from obese hosts were even more glycolytic, we assessed the effector function of tumor-infiltrating lymphocytes (TILs). We purified TILs using the Ficoll-Paque gradient and stimulated them with PMA/ionomycin. We found that tumors from obese hosts contained fewer IFN- γ^+ CD4⁺ T cells (Figures 1D and 1E). Our prior study using human HNSCC tissue suggests that PD-1⁺ T cells are activated effectors.^{36,37} We found that tumors from obese mice also contained fewer PD-1⁺CD4⁺ T cells (Figures 1F and 1G). In agreement, the overall frequency of CD8⁺ T cells was significantly lower in tumors grown in obese mice (Figures 1H and 1I).

Obesity establishes an intra-tumoral immune landscape that dampens Th1 polarization

The generation of effector T cells is the culmination of a series of immunological reactions starting from the activation of antigenpresenting cells. To characterize obesity-associated TME alteration at a high resolution, we harvested five tumors from the control diet group and five tumors from the high-fat diet group. After we sorted out live CD45⁺ immune cells from the tumor single-cell suspension, we mixed about an equal number of immune cells from each tumor sample together to ensure a balanced representation. The two pools of TILs were then subjected to singlecell RNA sequencing (scRNA-seq). After filtering, we integrated 5,154 high-quality transcriptomes and identified 20 distinct cell clusters (Figure 2A). Most of the TILs in the MOC2-E6/E7 model consisted of four suppressive myeloid cell subsets with complementary features. The first suppressive myeloid subset included clusters 1, 2, 4, 5, and 7. These MDSCs expressed high levels of Ly6g and PD-L1. The second subset, cluster 14, consisted of granulocytic MDSCs with high expression levels of Cox2. The third myeloid cell subset consisted of clusters 3 and 10 and was defined by high expression levels of CD206 and Arginase 1 (Arg1). The fourth suppressive myeloid cell subset cluster 17 expressed high levels of Tgfb1 but low levels of PD-L1. In addition, there were two myeloid cell subsets that were maintained by IFN-I signaling. The first subset was cluster 6 with high expression levels of Sting, CD40, CD86, and IFN-I target genes, such as Cxcl9, Cxcl10, lsg15, and Mx1. The other subset was conventional dendritic cell type 1 (cDC1), which included clusters 12 and 18. There were only a limited pool of T cells (clusters 11, 13, and 19), consistent with the hypoimmunogenic nature of this model. Each cluster was associated with a distinct transcriptional profile (Figure 2B, Table S1).

Next, we examined the relative percentage of the myeloid and lymphoid compartments. High-fat-diet-induced obesity triggered myeloid compartment expansion and lymphoid clusters contraction in the TME (Figures 2C and 2D). Specifically, we found that the activated myeloid cells with high expression levels of Sting and IFN-I signatures were reduced by 66.1% in tumorassociated myeloid cells (TAMs) from obese mice, representing a reduction of 11.9% of total infiltrating immune cells in the regular diet group to 4.0% in the high-fat diet group (Figure 2E). In contrast, there was a 50.8% increase in CD206⁺Arg1⁺ TAMs (cluster 3), a 48.7% increase in Cox2+ granulocytic MDSCs (cluster 14), and a 20% contraction of an IFN-I-maintained cDC1 subset (cluster 18) in TILs from obese mice. Ki67⁻T-bet⁺ effector T cells (cluster 11) and Ki67⁺T-bet⁺ effector T cells (cluster 19) were reduced by 37.8% and 34.5% in the TILs from obese hosts, respectively (Figure 2E). To better assess the effector functional state of intra-tumoral T cells, we first compared the expression of T-bet, a master transcription factor for Th1 development. Intratumoral T cells from obese hosts expressed lower levels of T-bet. The median expression levels of Gmzb and Ifng in T cells isolated from tumors in obese mice were 25.1% and 50.1% of those in the TILs from lean hosts. In contrast, the levels of Th2 cytokines, such as II4 and IL10, in T cells from TILs in obese mice were higher (Figure 2F).

Saturated fatty acids, but not unsaturated fatty acids, dampen STING-mediated immune activation

As our immune profiling of HNSCC from normal and obese mice suggests that obesity leads to an IFN-I-deprived phenotype, we next sought to investigate the mechanism of obesity-mediated Th1 suppression. Palmitate, an ester of palmitic acid, is used to model the effects of obesity.38-40 Palmitate accounted for 61% of the total saturated fatty acids in the high-fat diet. To examine both cancer cell and immune cell responsiveness to saturated fatty acids, we pretreated both MOC2-E6/E7 cells and BMDMs with either carrier alone, i.e., 10% bovine serum albumin (BSA), or 200 μM palmitate-BSA for 24 h, as previously described $^{\rm 40,41}$ for 24 h. We previously showed that MOC2-E6/ E7 cancer cells express HPV16 E7, which promotes the turnover of STING, and are inert to STING agonists, cyclic dinucleotides (CDNs) and that STING protein needs to be expressed to bypass intrinsic cancer suppression of this pathway.^{5,6} Indeed, the relative expression of STING levels was much lower in MOC2-E6/E7 cells than BMDMs (Figure S1A). Thus, we transfected 1.0 µg/mL STING expression plasmid in MOC2-E6/E7 cells 16 h prior to qPCR analysis of the IFN-I gene signatures including Ifnb1,

Figure 2. Obesity establishes an intra-tumoral immune landscape that dampens Th1 polarization

(A) Tumors from normal-weight and obese mice were harvested at day 21 after implantation. $CD45^+$ tumor-infiltrating immune cells were FACS sorted and pooled (n = 5 mice/condition) and subjected to single-cell RNA sequencing. After filtering, 5,154 high-quality transcriptomes were integrated for UMAP analysis. Divergent myeloid, lymphoid, and epithelial lineages were defined by the top 2,025 genes with the highest cell-to-cell variation.

(B) Clusters displayed from (A) showed distinct gene expression patterns.

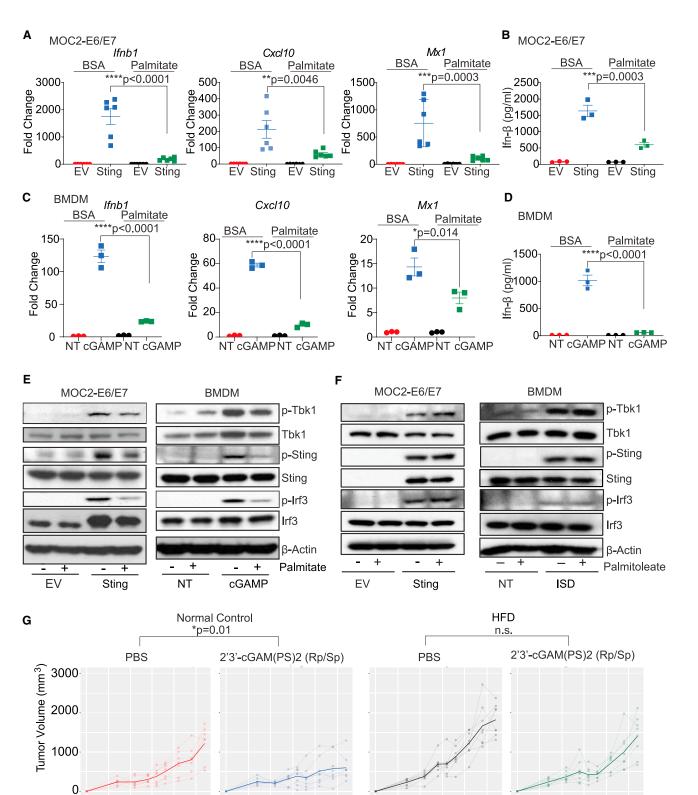

(C) The size of myeloid and lymphoid compartments in TILs separated from lean and obese hosts are shown.

(D) The absolute size (left) and relative percentage of each cluster (right) in TILs separated from lean and obese mice are shown.

(E) The frequencies of cluster 6 (STING⁺ myeloid cells), cluster 3 (CD206⁺Arg1⁺ M2-like macrophages), and cluster 14 (Cox2⁺ granulocytic MDSCs), as well as clusters 11 and 19 (Tbet⁺ T cells) are shown for TILs separated from lean control and obese mice.

(F) The expression levels (Log) of *Tbet*, *Gzmb*, *Ifng*, *II4*, and *II10* were compared between T cells (clusters 11, 13, and 19) in TILs separated from lean control and obese mice using the R-package stats (*p < 0.05, **p < 0.01, ****p < 0.0001).

Cxcl10, and Mx1. We found that STING expression induced high levels of transcription of Ifnb1 and its target genes Cxc/10 and Mx1, as expected. Palmitate nearly abrogated STING-mediated cytokines transcription (Figure 3A). To substantiate the finding, we performed ELISA of the supernatant and found that palmitate significantly inhibited STING-induced IFN-ß production (Figure 3B). Intra-HNSCC TAMs do not suffer from epithelial oncogenes-mediated STING suppression. Thus, we then generated BMDMs to test the effect of palmitate on CDNs-induced immune activation. We transfected BMDMs with 1.0 µg/mL cyclic di-GMP-AMP (cGAMP) and incubated for 16 h. Consistent with our findings in tumor cells, palmitate significantly inhibited cGAMP-induced gene transcription and nearly abrogated IFNβ protein production, as measured by qPCR and ELISA, respectively (Figures 3C and 3D). To characterize STING signaling, we performed immunoblots using lysates from treated MOC2-E6/ E7 cells and BMDMs. We found that palmitate reduced the hallmarks of STING activation, including the phosphorylation of TBK1, IRF3, and STING (Figure 3E). To assess whether this link is unique to palmitate, we also treated MOC2-E6/E7 cells and BMDMs with 200 µM myristate, which is another common form of saturated fatty acids in the experimental high-fat diet. Then, we expressed STING in MOC2-E6/E7 cells and treated BMDMs with cGAMP to induce STING signaling. Myristate exposure suppressed the phosphorylation of Tbk1, Sting, and Irf3, similar to palmitate incubation (Figures S1B and S1C).

To assess the specificity of saturated fatty acid-mediated suppression of the STING-IFN-I pathway, we tested whether unsaturated fatty acids can also regulate this pathway. Palmitoleic acid is a monounsaturated ω-7 fatty acid. It is one of the most common unsaturated fatty acids in the experimental high-fat diet and adipose tissue. As with palmitate, we treated MOC2-E6/E7 cells with BSA alone or 200 μ M palmitoleate-BSA for 24 h, followed by transfection of 1.0 µg/mL STING expression plasmid. Palmitoleate incubation had no effect on STING-mediated IFN-I signaling (Figure 3F). We also incubated BMDMs with 200 μ M palmitoleate for 24 h and transfected cells with 2.0 µg/mL STING agonist. Palmitoleate did not reduce the phosphorylation of Tbk1, Sting, and Irf3 (Figure 3F). Then, we sought to determine whether this observation could be extrapolated into other unsaturated fatty acids. Oleic acid is a monounsaturated ω-9 fatty acid found in various dietary sources. As with palmitate, we treated MOC2-E6/E7 cells with carrier alone or 200 μ M

oleate-BSA for 24 h, followed by transfection of 1.0 μ g/mL STING expression plasmid. We found that oleate did not affect STING-mediated IFN-I response (Figure S1D). Similarly, we incubated BMDMs with 200 μ M oleate for 24 h and then transfected cells with 1.0 μ g/mL cGAMP. Oleate did not modulate the magnitude of CDN-mediated immune activation (Figure S1E).

Although STING-inducing therapies have entered clinical trials, as either a single agent or a priming agent for ICB, it remains unclear whether underlying conditions, such as obesity, affect cancer response. Thus, we tested the effectiveness of a modified cGAMP, 2'3'-cGAM(PS)2, in our established HNSCC obesity model. 2'3'-cGAM(PS)2 was engineered to contain stereoisomers of phosphorothioate diester linkages, which are resistant to the hydrolysis activities of ENPP1. 2'3'-cGAM(PS)₂ has shown significantly improved anti-tumor activity in vivo.⁴² Mice were fed either a regular chow diet (consisting of 11.4% kcal fat content) or a 60% kcal high-fat diet for twelve weeks prior to implantation of MOC2-E6/E7 tumor cells. Then, we treated mice intratumorally (i.t.) with either PBS or 2.5 μ g 2'3'-cGAM(PS)₂ seven days post-implantation, once per week for three weeks. In agreement with previous reports, intra-tumoral injection of 2'3'-cGAM(PS)₂ reduced tumor burden in mice on the regular diet. Six of seven mice showed a response. The therapeutic effectiveness was reduced significantly in tumor-bearing obese mice (Figure 3G). Collectively, these data suggest that saturated fatty acids, but not unsaturated fatty acids, have a profound negative impact on the activation of the STING-IFN-I pathway and that obesity negatively affects the therapeutic effectiveness of CDNs in vivo.

Myeloid cells from obese hosts were insensitive to STING stimulation and were more suppressive to T cell activation

So far, we have shown that obesity expands the quantity of TAMs and saturated fatty acids dampen the STING response in normal myeloid cells *in vitro*. Next, we sought to characterize the quality of TAMs and myeloid cells separated from obese mice. The experimental high-fat diet model has known sexual dimorphism.⁴³ To make sure our observed tumor burden difference is consistent between both sexes, we established a lean and obese male mice model using the same method described above. Mouse weights were monitored longitudinally for more than 100 days and the high-fat diet group showed significantly more weight gain during the observation window (Figure 4A). In

Figure 3. Saturated fatty acids, but not unsaturated fatty acids, dampen STING-mediated immune activation

(A and B) MOC2-E6/E7 cells were pretreated with mock (BSA only) or 200 μ M palmitate-BSA for 24 h then transfected with 1.0 μ g/mL mouse Sting expression plasmid for 16 h. (A) RNA was isolated and expression of murine *Ifnb1*, *CxcI10*, and *Mx1* was assessed via qPCR. The experiment was repeated twice, and values represent mean \pm SEM of six biological replicates per sample. (B) Supernatant was collected and assessed for the presence of IFN- β via ELISA. Values represent mean \pm SEM of three technical replicates per sample. All comparisons were made using one-way ANOVA (**p < 0.01; ***p < 0.001).

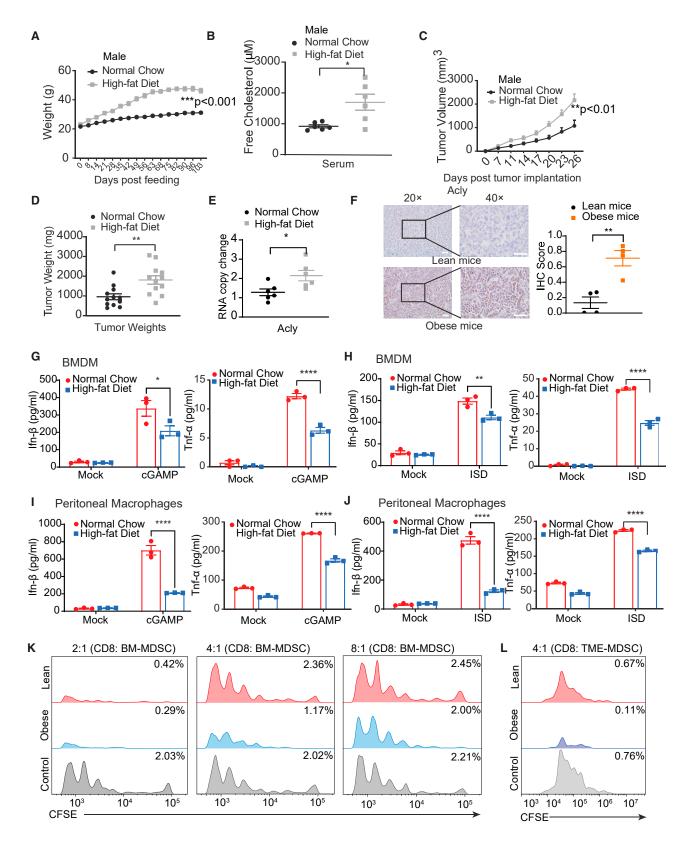

(E and F) MOC2-E6/E7 cells and BMDMs were primed with BSA only, 200 µM palmitate-BSA (E), or 200 µM palmitoleate-BSA (F) for 24 h and then transfected with the indicated STING agonists, 1.0 µg/mL mouse Sting, 1.0 µg/mL 2'3'-cGAMP, or 2.0 µg/mL ISD for 16 h. Cell lysates were subjected to SDS-PAGE for the indicated markers.

(G) One million MOC2-E6/E7 cancer cells were implanted subcutaneously into the right flank of normal-weight or obese mice 12 weeks post-high-fat diet feeding. One week later, either mock (PBS, 100 μ L) or 2.5 μ g 2'3'-cGAM(PS)₂ (Rp/Sp) was administered to mice i.t. once per week for 3 weeks. Tumors were measured every 2–4 days starting day 7 post-implantation. Tumor growth curves are compared among the groups (*p = 0.01, n.s. p > 0.05).

⁽C and D) Bone marrow-derived macrophages (BMDMs) were pretreated with mock (BSA only) or 200 μ M palmitate-BSA for 24 h then transfected with 1.0 μ g/mL 2'3'-cGAMP for 16 h. (C) RNA was isolated and expression of murine *lfnb1*, *Cxcl10*, and *Mx1* was assessed via qPCR. Values represent mean \pm SEM of three biological replicates per sample. (D) Supernatant was collected and assessed for the presence of IFN- β via ELISA. Values represent mean \pm SEM of three technical replicates per sample. All comparisons were made using one-way ANOVA (*p < 0.05; ****p < 0.0001).

(legend on next page)

addition, the mice from the high-fat diet group showed significantly elevated cholesterol levels in the serum (Figure 4B). Livers were harvested from mice in the lean and obese groups and stained with a lysochrome, oil red O, to quantitate fat deposition. As expected, there was significantly more fat accumulation in the livers of obese mice, further validating the model (Figure S2). Twelve weeks post-high-fat diet treatment, we implanted MOC2-E6/E7 tumors and found that obese mice suffered from a significantly higher tumor burden, consistent with the female mouse model (Figures 4C and 4D). To ensure that there is also increased fatty acid biosynthesis in the TME, we resected tumors and quantitated the levels of ATP citrate synthase (Acly) at both transcription and protein levels. We found that tumors from obese mice expressed higher levels of Acly (Figure 4E). In agreement, both tumor cells and infiltrating immune cells showed stronger Acly staining (Figure 4F), suggestive of elevated fatty acids synthesis in the TME of obese mice.

To better characterize the functional alteration of myeloid cells from obese hosts, we first generated BMDMs from bone marrows isolated from tumor-bearing lean and obese mice. We transfected the BMDMs with 2.0 µg/mL cGAMP and measured the levels of secreted IFN- β and tumor necrosis factor (TNF)- α in the supernatant by ELISA. The BMDMs from obese mice showed significantly lower levels of IFN- β and TNF- α , in response to cGAMP (Figure 4G). To further corroborate the findings, we transfected BMDMs from lean and obese mice with another STING agonist, 3.0 µg/mL interferon stimulatory DNA (ISD). BMDMs from obese mice showed significantly reduced transcription of IFN-I signatures, including Ifnb1, pan-Ifna, Cxcl10, Isg15, Isg54, and Mx1 (Figure S3A). In agreement, we found that BMDMs from obese mice produced significantly lower levels of IFN- β and TNF- α (Figure 4H). During the one-week differentiation period to generate BMDMs, the cells from the obese group were not exposed to any additional saturated fatty acids. To ensure direct physiological relevance, we also separated peritoneal macrophages from tumor-bearing lean and obese mice. We first transfected them with 2.0 µg/mL cGAMP and found an even more dramatic

reduction in STING-induced IFN- β secretion from peritoneal macrophages in the obese group (Figure 4I, left panel). Similarly, the peritoneal macrophages from obese mice were less capable of producing TNF- α , in response to cGAMP (Figure 4I, right panel). Then, we transfected the peritoneal macrophages from lean and obese mice with 3.0 µg/mL ISD and recapitulated our findings with BMDMs (Figure 4J). Interestingly, obesity-associated myeloid cell insensitivity was specific to STING stimulation. Next, we transfected BMDMs and peritoneal macrophages isolated from tumor-bearing lean and obese mice with 1.0 µg/mL 5'ppp-dsRNA, which specifically activates MAVS- but not STING-mediated IFN-I production, and incubated for 16 h. We did not see a difference between the cells from lean and obese mice (Figure S3B).

Finding that myeloid cells from obese mice are insensitive to STING stimulation, we next sought to characterize the functional profiles of MDSCs, which were expanded in the TME from obese hosts. Using a previously described protocol,⁴⁴ we generated bone marrow-derived MDSCs (BM-MDSCs) by culturing bone marrow cells for four days with 200 U/mL GM-CSF. This treatment licensed cells into monocytes predisposed to suppression. Monocytes were then activated using a combination of 0.1 μ g/mL lipopolysaccharide (LPS) and 100 U/mL IFN- γ for 16 h. BM-MDSCs were purified by fluorescence-activated cell sorting (FACS) of live CD11b⁺Ly6g⁺ cells. We separated CD8⁺ T cells from the spleens of age-matched C56BL/6J mice, which were then labeled with 5.0 µM CFSE. BM-MDSCs were co-cultured with CD8⁺ T cells at 2:1, 4:1, and 8:1 ratios and treated with anti-CD3/CD28 beads. Following a four-day co-culture, a very high number of BM-MDSCs (2:1) ratio from either group can repress CD8⁺ T cell proliferation, with the BM-MDSCs from obese mice being more suppressive (Figure 4K, left panel). The BM-MDSCs from obese mice also showed more suppressive activity than those separated from lean mice when co-cultured with CD8⁺ T cells at 4:1 and 8:1 ratios. To validate this finding, we FACS sorted MDSCs from the tumors grown in lean and obese mice (TME-MDSC) and co-cultured them with purified

Figure 4. Myeloid cells from obese hosts were insensitive to STING stimulation and were more suppressive of T cell activation

(A) Six-week-old male C57BL/6 mice were fed either a normal (11.4% kcal fat) or high-fat (60% kcal fat) diet for twelve weeks prior to tumor implantation. Body weights were monitored for >100 days (n = 12 in regular diet group and n = 12 in high-fat diet group). Body weight differences between groups were assessed using the generalized estimating equation model (**p < 0.001).

(B) Serum samples were collected from both groups and free cholesterol levels measured (*p < 0.05).

(C) One million MOC2-E6/E7 cancer cells were then implanted subcutaneously into the right flank of the mice. Tumor size was measured every 2–4 days. Tumor burden between groups was compared using the generalized estimating equation model (*p < 0.01).

(D) Tumors were harvested and weighed (**p < 0.01).

(E) Total RNA was isolated from excised pieces of tumors. The transcripts of *Acly* were quantified via qPCR (n = 6 lean mice; n = 6 obese mice). Values represent mean \pm SEM of three technical replicates per tumor (*p < 0.05).

(F) Immunohistochemistry (IHC) was performed to assess the protein levels of Acly in tumors grown in lean and obese mice. IHC was scored by ImageJ. Scale bar, 200 μ m. Values represent mean \pm SEM of four representative staining per group. The comparison between the two groups was made using a two-tailed unpaired t test (**p < 0.01).

(G–J) BMDMs (G and H) and peritoneal macrophages (I and J) from lean and obese mice were transfected with 2.0 μ g/mL cGAMP or 3.0 μ g/mL ISD and incubated for 16 h. The supernatants were collected from each group and assessed for the protein levels of secreted IFN- β and TNF- α using ELISA. Values represent mean \pm SEM of three technical replicates per sample. The experiment was repeated to confirm all findings. Comparisons were made using two-way ANOVA, followed by multi-comparison tests (*p < 0.05, **p < 0.01, ****p < 0.0001).

(K) BM-MDSCs from lean (n = 4) and obese (n = 4) mice were cultured in 200 U/mL GM-CSF media for 4 days and then activated using 0.1 μ g/mL LPS and 100 U/mL IFN- γ for 16 h. CFSE-labeled CD8⁺ T cells were co-cultured with BM-MDSCs for 4 days and then analyzed by flow cytometry for proliferating CFSE⁺CD8⁺ T cells.

(L) TME-MDSCs were isolated from lean (n = 5) and obese (n = 6) tumor-bearing mice using FACS of CD11b⁺Ly6G⁺ cells. TME-MDSCs were co-cultured with CSFE-labeled CD8⁺ T cells for 4 days and then analyzed by flow cytometry for proliferating CFSE⁺CD8⁺ T cells.

CD8⁺ T cells at a 4:1 ratio. We found that the TME-MDSCs from tumors grown in obese mice were much more suppressive than those from the tumors grown in lean mice (Figure 4L).

Saturated fatty acids induce the expression of NLRC3 to antagonize STING signaling

To identify a molecular link that underpins saturated fatty acidspotentiated suppression of the STING-IFN-I response, we examined a panel of nucleotide-binding, leucine-rich repeats-containing (NLR) genes, which have emerged as central regulators of innate immune response and metabolism.45-47 We extracted RNA from homogenized tumors from control and obese mice and assessed two pro-inflammatory NIr genes (NIrp3 and Nod2) and three anti-inflammatory regulator NIr genes (NIrp12, NIrx1, and NIrc3). These NIr genes were selected because of their reported roles in regulating IFN-I production,⁴⁸⁻⁵² which is dampened by saturated fatty acids. We found that NIrc3 was the only gene in this panel that was significantly upregulated in obese tumors (Figure 5A). To confirm this finding, we first stained the tumors grown in lean and obese mice with an anti-NIrc3 antibody. We found that cancer cell-specific NIrc3 expression was significantly elevated in the obese group (Figure 5B). Then, we also assessed the expression levels of NIrc3 in TAMs. We analyzed the single-cell dataset presented in Figure 2 and found that NIrc3 expression levels were significantly higher in the TAMs from tumors grown in obese hosts, including cluster 3 (CD206⁺Arg1⁺), cluster 7 (PD-L1⁺), cluster 14 (Cox2⁺), and cluster 17 (Tgfb1⁺) (Figure 5C). These findings suggest that obesity upregulated the expression levels of NIrc3 in both cancer cells and TAMs. Because the STING-suppressive role of NLRC3 in myeloid cells has been reported,⁵³ here we focus on whether NLRC3 senses saturated fatty acids and dampens IFN-I production in cancer cells. We performed reciprocal co-immunoprecipitation using HA-tagged NLRC3 and FLAG-tagged STING in PCI13, FaDu, and UMSCC22A cells. NLRC3 strongly interacted with STING in HNSCC cells under stringent buffer conditions (Figures 5D, 5E, and S4A), in agreement with previous findings in HEK-293T cells.⁵² Then, we generated NLRC3-deficient human HNSCC cells using CRISPR-Cas9 lentiviruses. Due to frequent intrinsic inhibition of the STING-IFN-I pathway, we found that human HNSCC cells often fail to respond to the physiologic ligand of STING, CDNs.⁵ Thus, we tested two additional approaches that can activate the STING pathway. We first transfected empty vector (EV) control and *NLRC3*-deficient PCI-13 cells with 1.0 μ g/mL STING expression plasmid or 1.0 μ g/mL poly(dA:dT) 16 h prior to RNA harvesting. We found that *NLRC3* loss led to significantly increased expression of the STING-mediated IFN-I gene signatures *ISG15*, *MX1*, and *ISG54* (Figures 5F–5H and S4B). Similarly, we used the same approach to repress NLRC3 expression in FaDu cells. A defect in *NLRC3* enhanced STING- and poly(dA:dT)-induced immune activation (Figures 5I–5K and S4B).

To model the impact of NLRC3 on HNSCC immunogenicity, we then knocked down NIrc3 in MOC2-E6/E7 cells, confirmed by qPCR and immunoblots (Figures 6A and 6B). An alamarBlue assay showed that there were no differences in growth rates between the EV- and NIrc3-deficient tumor cells (Figure 6C). To substantiate the link between saturated fatty acids sensing and NIrc3-mediated suppression of the STING pathway, we first treated MOC2-E6/E7 cells with either carrier BSA or 200 µM palmitate-BSA. We found that palmitate significantly increased the expression levels of NIrc3 (Figures 6D and 6E). Then, we transfected EV- and NIrc3-deficient tumor cells with either 1.0 µg/mL STING expression plasmid or 1.0 µg/mL poly(dA:dT) for 16 h. NIrc3-deficient cells exhibited significantly increased expression levels of Ifnb1, Cxcl9, Cxcl10, and Mx1 from both STING-transfected samples (Figure 6F) as well as samples treated with poly(dA:dT) (Figure 6G). Last, we characterized the impact of NIrc3 on STING signaling by immunoblots. We found that a defect in NIrc3 resulted in much higher levels of the signaling hallmarks of STING activation, including the phospho-Tbk1 and phospho-Irf3, in response to either STING expression or poly(dA:dT) transfection (Figures 6H and 6I).

NIrc3 inhibits HNSCC immunogenicity in an IFN-Idependent fashion

To assess whether NIrc3 regulates the immunogenicity of HNSCC, we first implanted one million EV- or shNIrc3-MOC2-E6/E7 cancer cells subcutaneously in normal C57BL/6 mice.

Figure 5. Saturated fatty acids induce the expression of NLRC3 to antagonize STING signaling in human HNSCC cells

(A) Total RNA was isolated from whole excised tumors to quantify the mRNA expression levels of *NIrp3*, *Nod2*, *NIrp12*, *NIrx1*, and *NIrc3* (n = 8 normal-weight mice; n = 6 obese mice). Values represent mean \pm SEM of three technical replicates per tumor. All comparisons between the two groups were made using a two-tailed unpaired *t* test (n.s. p > 0.05; *p < 0.05).

(B) Tumors from obese and lean mice were harvested for H&E and NLRC3 IHC staining. Representative H&E and IHC staining patterns are shown. NLRC3 staining intensity was quantitated using ImageJ. Scale bar, 200 μ m. Values represent mean \pm SEM of four representative staining per group. The comparison between the two groups was made using a two-tailed unpaired t test (*p < 0.05).

(C) The expression levels of NIrc3 (Log) in tumor-associated myeloid cells, including clusters 3, 7, 14, and 17, were compared between lean and obese mice. (*p < 0.05, ***p < 0.001, ****p < 0.0001).

(D and E) Human HNSCC cell lines PCI-13 and FaDu were transfected with $1.0 \mu g/mL$ human HA-NLRC3 and FLAG-STING plasmids. STING and NLRC3 proteins were pulled down using anti-FLAG M2 affinity gel and anti-HA agarose, respectively. Immunoblots were performed for the indicated proteins.

(F) PCI-13 cells were transduced with empty vector (EV) or *NLRC3*-targeted CRISPR-Cas9 lentiviruses. Stable cell lines were generated via puromycin selection. Immunoblots and qPCR were used to confirm the knockout efficiency. Comparison between the two groups was made using a two-tailed unpaired t test (*p < 0.05). (G and H) EV and *NLRC3^{-/-}* PCI-13 cells were transfected with either 1.0 μ g/mL human STING expression plasmid (G) or 1.0 μ g/mL poly(dA:dT) (H) for 16 h. The mRNA levels of human *ISG15* and *MX1* were assessed via qPCR. Values represent mean ± SEM of three biological replicates per sample.

(I and J) FaDu cells were transduced with EV or *NLRC3*-targeted CRISPR-Cas9 lentiviruses. Stable cell lines were generated via puromycin selection. Proteins and total RNA from cells were isolated and the knockout efficiency of *NLRC3* quantified via immunoblots and qPCR, respectively. EV and *NLRC3^{-/-}* FaDu cells were transfected with either 1.0 μ g/mL human STING expression plasmid (J) or 1.0 μ g/mL poly(dA:dT) (K) for 16 h. The expression levels of human *ISG15* and *MX1* were assessed via qPCR. Values represent mean \pm SEM of three biological replicates per sample. Data represent two experiments. Comparisons were made using one-way ANOVA followed by multi-comparison tests (**p < 0.01; ****p < 0.0001).

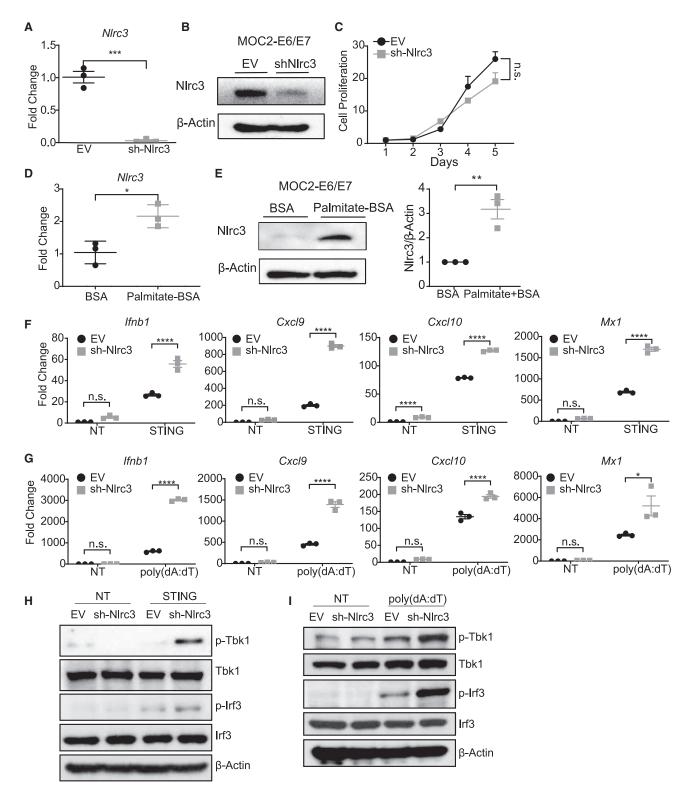

Figure 6. NLRC3 inhibits the STING-IFN-I pathway in murine HNSCC cells

(A and B) MOC2-E6/E7 was transduced with an empty vector (EV) or *NIrc3*-targeting short hairpin RNA lentiviruses. Stable cell lines were generated via enhanced puromycin selection. Knockdown efficiency was confirmed via qPCR (A) and immunoblots (B). Comparisons between the two groups were made using a two-tailed unpaired t test (***p < 0.001).

We monitored tumor burden and found that a cancer-cell intrinsic loss of NIrc3 resulted in significantly delayed tumor growth (Figure 7A). To assess whether the observed tumor rejection in the NIrc3-deficient tumors was immune-mediated, we implanted EV control and NIrc3-deficient MOC2-E6/E7 cells into $Rag1^{-/-}$ mice, which were devoid of mature T cells and B cells. We found that the lack of adaptive immunity completely rescued the phenotype, with no differences found between the two groups (Figure 7B). Then, we implanted the control and NIrc3deficient tumors in Ifnar1^{-/-} mice, which lacked the expression of the receptor for IFN-I. Similar to the Rag1^{-/-} hosts, few differences in tumor burden were found between the two groups (Figure 7C). These experiments suggest that cancer-cell intrinsic NIrc3-mediates HNSCC immunogenicity in an IFN-I-dependent fashion. Next, we homogenized tumor tissue from EV- and NIrc3-deficient MOC2-E6/E7-bearing C57BL/6 mice and assessed for the expression levels of Th1 cytokines associated with T cell recruitment and activation. We found that the expression levels of Cxcl9, Cxcl10, Tnf, and Ifng were significantly enhanced in NIrc3-deficient tumors (Figure 7D). We enriched TILs through Ficoll-Paque gradient centrifugation and found that cancer-cell intrinsic loss of NIrc3 resulted in the increased frequencies of overall T cells, $\gamma\delta$ T cells, and CD8+PD-1 low T cells, which we previously found to exhibit more robust effector functions (Figures 7E–7G).³⁷ As saturated fatty acids induced the expression of NIrc3 in cancer cells, serving as a possible link to suppress cancer immunogenicity, we next implanted NIrc3-deficient tumor cells into mice that were fed with regular chow or a 60% kcal high-fat diet for twelve weeks. High-fat diet induced significant body weight gain, as expected (Figure S4C). The difference in tumor burden that we observed between lean and obese mice using wild-type tumor cells was completely rescued (Figures S4D and S4E), suggesting that cancer-specific NIrc3 expression is a key link underpinning obesity-potentiated suppression of HNSCC immunogenicity.

DISCUSSION

The discovery of checkpoints of the adaptive immune system revolutionized cancer therapy by improving the effector functions of intra-tumoral T cells. With the ICB therapies targeting T cells being brought up to the first-line setting, it has become clear that the majority of tumors feature suppression of the innate immune sensing system, which leads to an insufficient pool of intra-tumoral antigen-specific T cells for developing an optimal response. Thus, the identification of cancer checkpoints

involving the innate immune sensing pathways is essential to designing new innate immune priming strategies and expanding the pool of responders to immunotherapy.

Recent studies have suggested that multiple priming approaches exacerbate tumor DNA damage and engage the STING-IFN-I pathway for the remodeling of TME. For example, the inhibitors of DNA damage repair activate the STING-IFN-I pathway and sensitize cold cancers to ICB.54,55 External beam radiotherapy and targeted radionuclide therapy can also both activate STING-dependent IFN-I signaling to effectively prime cold cancers.⁵⁶ In fact, the efficacy of radiotherapy is largely lost in STING-deficient hosts.¹³ An epigenetic remodeling agent targeting a histone H3 lysine 9 trimethylation demethylase, KDM4A, sensitizes cold HNSCC to ICB by inducing replication stress-induced STING activation.⁵⁷ In addition, cancer-specific expression of STING is positively associated with patient outcomes in two independent clinical cohorts of HNSCC.⁵ Thus, the maintenance of cancer cell "STING fitness" underpins the immunogenicity of HNSCC.

Although oncogene-driven suppression of the STING-IFN-I pathway has been identified, it remains unclear whether metabolic comorbidities contribute to the editing of cancer immunogenicity. Multiple large independent prospective cohorts have recently presented an underappreciated link between obesity and the development of HNSCC,¹⁶⁻¹⁹ which entails the establishment of peripheral immune tolerance. To better understand the molecular mechanism linking obesity to reduced HNSCC immunogenicity, this study characterized a signaling axis that pinpointed NLRC3, an innate immune checkpoint NLR protein, serving as a saturated fatty acids responder. Saturated fatty acids, but not unsaturated fatty acids, potently inhibit STINGmediated immune activation. Many cancer cells, including HNSCC, show defective STING signaling and do not mount an IFN-I response upon CDN challenge.6,58 We, therefore, used STING plasmid expression as one of the stimuli. Even with this strong STING stimulation, palmitate, but not oleate, nearly abrogated immune activation. NLRC3 undergoes adaptive upregulation in response to palmitate and negatively impacts HNSCC immunogenicity. NLRC3-deficient tumors were rejected by the adaptive immune system in an IFN-I-dependent fashion. NLRC3 binds to cytoplasmic DNA species, releasing its interaction with STING and licensing the downstream IFN-I generation process.^{52,53}

Obesity creates an IFN-I-deprived TME, which drives *de novo* development and influx of MDSCs to HNSCC. We characterized the impact of obesity on TME at single-cell resolution and

⁽C) The proliferation of EV control and sh-Nlrc3-MOC2-E6/E7 cells was assessed using an alamarBlue assay. Each group included five replicate wells. Comparisons at endpoint were made using a two-tailed unpaired t test (n.s. p > 0.05).

⁽D and E) *NIrc3* expression was measured in MOC2-E6/E7 cells treated with either BSA alone or 200 μ M palmitate-BSA for 24 h via qPCR (D) and immunoblots (E). Densitometry analysis was performed using ImageJ and is shown in the right panel (E). Comparisons between two groups were made using a two-tailed unpaired t test (*p < 0.05, *p < 0.01).

⁽F and G) EV- and sh-Nlrc3-MOC2-E6/E7 cells were transfected with either (F) 1.0 μ g/mL Sting expression plasmid or (G) 1.0 μ g/mL poly(dA:dT) for 16 h. Total RNA from cells was isolated. Expression of murine *lfnb1*, pan-*lfn\alpha*, *Cxcl9*, *Cxcl10*, and *Mx1* was assessed via qPCR. Values represent mean \pm SEM of three biological replicates per sample. Experiments were performed twice. Comparisons were made using one-way ANOVA followed by multi-comparison tests (*p < 0.05; ****p < 0.0001).

⁽H and I) EV- and sh-Nlrc3-MOC2-E6/E7 cells were transfected with either 1.0 µg/mL mouse Sting expression plasmid (H) or 1.0 µg/mL poly(dA:dT) (I) for 16 h. Cell lysates were subjected to SDS-PAGE for the indicated markers.

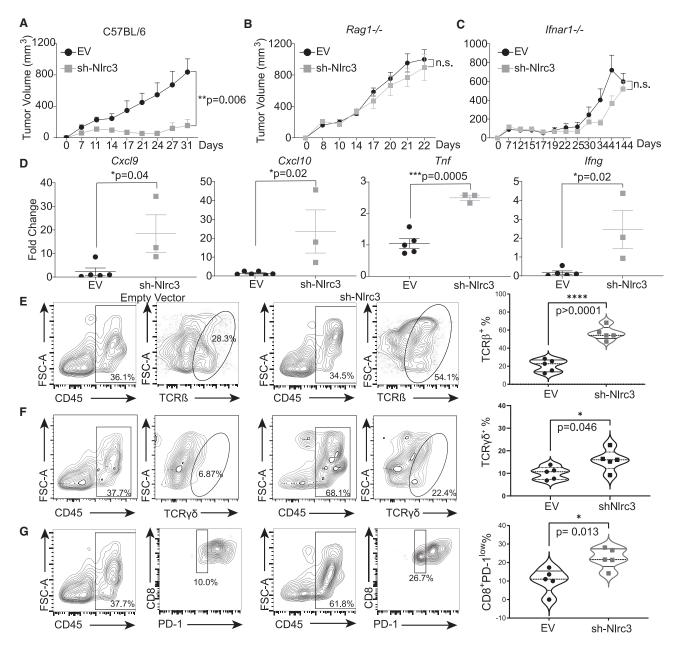

Figure 7. NLRC3 inhibits HNSCC immunogenicity in an IFN-I-dependent fashion

(A) One million EV- or sh-Nlrc3-MOC2-E6/E7 cancer cells were implanted subcutaneously (s.c.) into the right flank of 13-week-old C57BL/6 mice and monitored for tumor burden (n = 5 mice per group). Tumor measurements occurred every 2–4 days. Experiments were conducted twice. Differences between groups were assessed using the generalized estimating equation model (**p < 0.01).

(B) One million EV- or sh-Nlrc3-MOC2-E6/E7 cancer cells were implanted s.c. into the right flank of six-week-old Rag1^{-/-} mice and monitored for tumor burden (n = 5 per group). Tumor measurements occurred every 2–4 days.

(C) One million EV- or sh-NIrc3-MOC2-E6/E7 cancer cells were implanted s.c. into the right flank of six-week-old *lfnar1^{-/-}* mice that were backcrossed to C57BL/ 6J for over nine generations and monitored for tumor burden (n = 7 per group). Differences between groups were assessed using the generalized estimating equation model (n.s. p > 0.05).

(D) Total RNA was isolated from one representative set of whole excised tumors and quantified for the mRNA expression levels of *Cxcl9*, *Cxcl10*, *Tnf*, and *Ifng* (n = 5 mice with EV-MOC2-E6/E7 tumors; n = 3 mice with sh-NIrc3-MOC2-E6/E7 tumors due to complete tumor regression). Values represent mean \pm SEM of three technical replicates per tumor. All comparisons between two groups were made using a two-tailed unpaired t test (*p < 0.05; ***p < 0.001).

(E–G) TILs from one representative set of experiments were isolated and analyzed by flow cytometry. The gating strategy for all experiments was as follows: Lymphocytes, single cells, Zombie Aqua negative (viability), $CD45^+$ (n = 5 mice per condition). Comparisons between two groups were made using a two-tailed unpaired t test (*p < 0.05, ****p < 0.0001).

revealed a massive expansion of suppressive myeloid cell clusters in the TILs from obese hosts. These myeloid clusters assume diverse complementary features. Only a subset of these suppressive myeloid cells expresses PD-L1 or Galectin-9. Other suppressive cells feature high expression levels of Tgfb1, Arg1, or Cox2. TILs from obese hosts showed more Cox2⁺ MDSCs, more CD206⁺Arg1⁺ myeloid cells, and fewer STING⁺ myeloid cells. As a result, effector T cells within the TME of obese hosts are both fewer and less functional. STING agonists have been evaluated for their potency in reducing tumor burden by reprogramming the myeloid compartment in a variety of tumor models.⁵⁹ Myeloid cells are generally considered to be the main target of intra-tumoral CDN injections. Notably, our findings show that not all myeloid cells will respond to CDNs. BMDMs and peritoneal macrophages separated from the obese hosts are largely refractory to STING agonists. The MDSCs from obese mice are also more suppressive. In agreement, intra-tumoral injection of a potent stable STING agonist lost efficacy in obese mice. Interestingly, obesity-mediated reprogramming of myeloid cells appears to be specific to the STING pathway because these cells retain their sensitivity to RIG-I agonists. To further corroborate the mechanistic link between obesity and NLRC3mediated STING suppression, we found that NLRC3-deficiency rescued the tumor growth difference between lean and obese hosts. As many priming strategies rely on the STING pathway, future studies would be informative to assess strategies to overcome obesity-induced desensitization to STING priming.

Limitations of the study

The clinical data on the impact of obesity on HNSCC response to ICBs are still limited. Several considerations in clinical study design may help better characterize the impact of common metabolic comorbidity on tumor immunogenicity. First, many HNSCC patients show bodyweight fluctuations around the time of diagnosis due to cancer or associated habits. Many HNSCCs directly interfere with eating and swallowing. Thus, initial characterization using early-stage tumors may reduce the number of confounding factors. Indeed, among patients with T1-T2 HNSCC who underwent curative-intent resection, obesity was a significant negative prognosticator and obesityassociated white adipose tissue inflammation was associated with worse outcomes.^{60,61} Second, body mass index, although easily accessible, may not be the most accurate measurement for obesity. For example, trained athletes can have substantially increased body mass index yet are not obese. Thus, other measurements such as waist circumference, waist-to-hip ratio, and a peripheral blood lipid panel, may be assessed in the design. Last but not least, the medication history of statins should be considered. Recent findings show that inhibiting the cholesterol biosynthetic pathway activates the STING-IFN-I pathway.⁶² Conceptually in agreement, lipophilic statins show notable vaccine adjuvant effects and anti-tumor potency.⁶³ HPV⁺ HNSCC patients who were on statins also showed improved clinical outcomes.^{20,21}

In this study, we emphasized the role of NLRC3 in underpinning obesity-associated desensitization of cells to STING agonists. However, the high-fat diet model and *in vitro* treatments with saturated fatty acids modulate multiple pathways, such as

endoplasmic reticulum stress and insulin signaling. It would be helpful to assess additional molecular pathways that link obesity with IFN-I response. We focused on the cancer cell-specific role of NLRC3 in driving tumor immune escape. It is also possible that NLRC3 expression in host cells also contributes to obesitymediated tumor immunogenicity. Additional studies to examine the function of NLRC3 in different immune subsets using tumor models with obesity being a comorbidity will help further delineate the compartment-specific roles of NLRC3.

Overall, this study rendered a single-cell immune atlas for HNSCC growing in a high-fat environment and linked saturated fatty acids with DNA-binding, STING-inhibitory, innate immune checkpoint, NLRC3. Saturated fatty acids, but not unsaturated fatty acids, potently inhibited STING activation in both cancer cells and myeloid cells. Both BMDMs and peritoneal macrophages in obese hosts were desensitized to STING stimulation. MDSCs from obese hosts were also more suppressive of T cell activation. We found that cancer-cell intrinsic NLRC3 expression was a central regulator of HNSCC immunogenicity. Depletion of NLRC3 resulted in IFN-I-dependent tumor rejection and rescued the NLRC3-wild-type tumor growth difference between lean and obese mice. These results provide a mechanistic link between obesity and elevated risks for HNSCC.

STAR***METHODS**

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- RESOURCE AVAILABILITY
 - Lead contact
 - Materials availability
 - Data and code availability
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
 - Animal studies
 - Cell lines and treatments
 - Bone marrow-derived macrophages (BMDMs) isolation and differentiation
 - O Peritoneal macrophages isolation and differentiation
- METHOD DETAILS
 - Preparation of fatty acid conjugates
 - Gene expression qPCR & ELISA
 - Immunoblotting assays
 - Histology, immunohistochemistry, and oil red O staining
 - AlamarBlue assay
 - O Quantitation of serum cholesterol levels
 - Flow cytometry
 - MDSC functional assay
 - Single-cell immune profiling
- QUANTIFICATION AND STATISTICAL ANALYSIS

RESOURCE AVAILABILITY

Lead contact

Further information and requests for resources and reagents should be directed to and will be fulfilled by the lead contact, Yu Leo Lei (leiyuleo@umich.edu).

Materials availability

Plasmids, cell lines, and unique reagents and materials are available to investigators at non-profit institutions upon the establishment of a material transfer agreement. Reagent sharing with investigators at for-profit institutions will be implemented after a licensing agreement.

Data and code availability

- The single-cell RNA-Seq dataset of TILs from lean and obese hosts has been deposited at the NCBI Sequence Read Archive with BioProject ID PRJNA756027 (http://www.ncbi.nlm.nih.gov/bioproject/756027). The dataset is publicly available as of the date of publication. The accession number is listed in the key resources table.
- This paper does not report original code.
- Any additional information required to reanalyze the data reported in this work paper is available from the lead contact upon request.

CellPress

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Animal studies

All animal handling and procedures were performed in accordance with the animal ethics and protocols approved by the Institutional Animal Care and Use Committee (IACUC) at the University of Michigan (PR000008517 and PR000010232). Male and female C57BL/ 6J (RRID:IMSR_JAX:000664), female *Ifnar1^{-/-}* (RRID: IMSR_JAX:002216), and female *Rag1^{-/-}* (RRID:IMSR_JAX:002216) mice were purchased from The Jackson Laboratory at eight weeks of age and group-housed under specific pathogen–free conditions in a temperature- and light-controlled environment. *Ifnar1^{-/-}* mice were subsequently backcrossed nine generations into the C57BL/6J line. To establish the obese mouse model, C57BL/6J mice were fed either a normal diet (5L0D, LabDiet, 24.6% protein, 11.4% fat, 57.3% carbohydrate, 4.09 kcal/g) or a 60% kcal% fat diet (D12492, Research Diets, 20% protein, 60% fat, 20% carbohydrate, 5.21 kcal/g) for twelve weeks before tumor implantation. As sex is not a known prognosticator for HNSCC, both sexes were used. Syngeneic HNSCC models were established by inoculation of one million empty vector control, shNLRC3, or wild-type MOC2-E6/E7 cells subcutaneously in the right flank of mice. To test drug efficacy, three weekly doses of either mock (PBS, 100 µL) or 2'3'-cGAM(PS)₂ (Rp/Sp) (50 µg/100 µL; catalog no. tlrl-nacga2srs, InvivoGen) were administered intratumorally. Notably, littermate controls of the same sex were randomly assigned to treatment groups. Beginning on day seven after tumor implantation, tumors were measured using a digital Vernier caliper every two-to-three days, and tumor volume was calculated according to the formula 1/2 (length × width²). All mice were euthanized at the indicated time points. After euthanasia, tumors, TILs, livers, sera, and spleens of the mice were harvested for subsequent analysis.

Cell lines and treatments

The HNSCC cell line PCI-13 (RRID:CVCL_C182) was derived from a male patient and acquired from the University of Pittsburgh. The HNSCC cell line UMSCC22A (RRID:CVCL_7731) was derived from a female patient and acquired from the University of Michigan. The HNSCC cell line FaDu (RRID:CVCL_1218) was derived from a male patient and purchased from ATCC. All human cell lines were authenticated and maintained in DMEM (10-013-CV, Corning) supplemented with 10% FBS (Gibco, Life Technologies), 100 U/mL penicillin (Gibco), and 100 mg/mL streptomycin (Gibco). The MOC2-E6/E7 (RRID:CVCL ZD33) cell line was derived from a female mouse and acquired from Harvard University. MOC2-E6/E7 was authenticated and cultured in 60% IMDM (SH30228.01, HyClone) with 30% F12 nutrient mix (11764-054, Gibco), 5% FBS, 4 µg/mL puromycin, 5 µg/mL insulin, 40 ng/mL hydrocortisone, 5 ng/mL EGF, 100 U/mL penicillin, and 100 mg/mL streptomycin. We generated NLRC3-targeting CRISPR-Cas9 lentiviruses, using a single-guide RNA (sgRNA): 5'-CCGGGTCTCCATCACTATCG-3'. NLRC3-knockout cells were established by transduction of HNSCC cells (PCI-13, FaDu) with the NLRC3-targeting CRISPR/Cas9 lentivirus. Control cells were transduced with empty vector virus that did not express the sgRNA sequence. gPCR on human NLRC3 was performed to validate the knockdown efficiency. EV-MOC2-E6/E7 and shNlrc3-MOC2-E6/E7 cell lines were transduced with empty vector control (EV) or shNlrc3-expressing lentiviruses (MilliporeSigma) followed by enhanced puromycin selection due to MOC2-E6/E7 cell-intrinsic low puromycin resistance (concentration of 120 µg/mL). Puromycin was purchased from InvivoGen (ant-pr-1). qPCR on murine NIrc3 was performed to validate the knockdown efficiency. Type I interferon pathway activation was assessed in vitro via the following agonists: 2'3'-cGAMP (tlrl-nacga23-1, InvivoGen); ISD naked (tirl-isdn, InvivoGen); Poly(dA:dT) (tirl-patn-1, InvivoGen); pcDNA3.1-human STING-HA and pcDNA3.1-murine STING-HA were provided by Glen N. Barber of the University of Miami.

Bone marrow-derived macrophages (BMDMs) isolation and differentiation

BMDMs were isolated from both adult female and male mice to assess type-I interferon responses in immune compartments. In brief, mice were euthanized, after which the two posterior femurs, tibias, and fibulas were resected from mice, using scissors and forceps sterilized with 70% ethanol, and placed within the biosafety cabinet. Bone ends were subsequently cut, and bone marrow was flushed out in sterile PBS using a 27G needle (305109, BD) and filtered through a 70- μ m cell strainer to achieve a single-cell suspension. Cells were spun down and resuspended in 5 mL of BMDM differentiation media (RMPI media with L-glutamine containing 20% heat-inactivated FBS, L-929 cell supernatant, and 1% penicillin/streptomycin). Cells were split into five 100 mm tissue culture-treated Petri dishes containing a final volume of 10 mL per plate. On day three post-plating, an additional 10 mL differentiation media was added to aid cellular growth. On day six post-plating, media was removed, and dishes were washed once with 1× PBS. Cells were then gently removed from the plate in 5 mL 1× PBS using a 25 cm cell scraper, spun down, and counted. Cells were plated for experimental use in 6-well tissue culture plates, 0.5×10^6 cells/well in 2 mL BMDM culture media (RPMI media with L-glutamine containing 20% heat-inactivated FBS and 1% penicillin/streptomycin).

Peritoneal macrophages isolation and differentiation

Peritoneal macrophages were isolated from male mice to assess myeloid cell sensitivity to agonists of the STING-IFN-I pathway. Mice were euthanized and mounted supine on a Styrofoam block. Using scissors and forceps, sterilized with 70% ethanol, the inner lining of the peritoneal cavity was exposed and injected with 5 mL of ice-cold PBS containing 3% FBS using a 27G needle. Briefly, the peritoneum was massaged to dislodge attached cells. A 25G needle was used to collect the fluid from the cavity and then inspected for blood contamination. An incision was made in the peritoneal cavity to collect any remaining fluid using a pipette. Samples were combined with regards to their groups, obese (n = 6) and lean (n = 6), spun down, and then plated in a 12-well tissue-culture dish,

1.6×10⁶ cells/well in 1 mL culture media (RPMI media with L-glutamine containing 20% heat-inactivated FBS and 1% penicillin/ streptomycin). The following day, media was aspirated, and the remaining adherent cells were used for downstream assays.

METHOD DETAILS

Preparation of fatty acid conjugates

To test the effects of free saturated and unsaturated fatty acids in modulating the type I interferon response, we prepared palmitate-BSA, palmitoleate-BSA, myristate-BSA, and sodium oleate-BSA conjugates. In brief, to prepare the BSA solution, 10% (w/v) fatty acid-free bovine albumin (A9418-5G, MilliporeSigma) was gradually added to ultrapure water at 52°C with gentle agitation until the BSA was fully dissolved. To prepare palmitate, palmitoleate, and myristate, palmitic acids (P0500, Sigma-Aldrich), palmitoleic acids (P9417, Sigma-Aldrich), and myristic acids (M3128, Sigma-Aldrich) were added to 0.1M NaOH (S2770, Sigma-Aldrich) and heated to 70°C until fully dissolved, yielding a concentration of 100 mM. Likewise, sodium oleate (O7501, Sigma-Aldrich) was added to ultrapure water at 55°C to yield a concentration of 100 mM. To conjugate fatty acids to BSA, the 100 mM stocks of palmitate, palmitoleate, myristate, and sodium oleate were added to 10% BSA at a ratio of 1:9 and heated at 55°C for 10 min. After conjugation, both the 10% (w/v) BSA solution and fatty acid-BSA solutions were filter-sterilized using a 0.45 μ m PES filter (SLHVR33RS, Fisher Scientific), aliquoted, and stored at -20°C. Before use, solutions were warmed to 37°C. For final use, 200 μ M of both fatty acid-BSA conjugates were used.

Gene expression qPCR & ELISA

For qPCR, total RNA was extracted using QIAshredder and the RNeasy Plus Mini Kit (catalog 79654 and 74134, respectively; Qiagen). RNA concentration was measured using a Nanodrop Spectrophotometer (Thermo Fisher Scientific). RNA was reverse-transcribed into cDNA using High-Capacity cDNA Reverse Transcription Kit and RNAse inhibitor (4368814 and N8080119, Applied Biosystems). The primers were synthesized by Integrated DNA Technologies. The primer sequences are shown in Table S2. For ELISA, supernatant from treated MOC2-E6/E7, BMDMs, and peritoneal macrophages was collected 16 h post-treatment with agonists of the type I interferon pathway. Protein levels of murine Ifn- β and Tnf- α in the supernatant were quantified using a LumiKineTM Xpress mIFN- β 2.0 kit (luex-mifnbv2, Invivogen) and Tnf- α Mouse ELISA kit (BMS6073, Invitrogen). The bioluminescent intensity was measured using a Synergy H1 microplate reader (Agilent) and Gen5 program (version 2.09), and three technical replicates per sample were examined simultaneously.

Immunoblotting assays

Whole-cell lysates per condition were harvested on ice in RIPA buffer (50 mM Tris-HCl pH 8.0 [BP1758500, ThermoFisher], 1% Triton X-100 [X100, Sigma-Aldrich], 0.05% SDS [74255-250G, Sigma-Aldrich], 0.25% deoxycholate [D6750, Sigma-Aldrich], 150 mM NaCl [S3014-5KG, Sigma-Aldrich], and 50 mM NaF [201154, Sigma-Aldrich]) supplemented with a protease inhibitor cocktail (11836170001, Roche) and Halt Phosphatase Inhibitor Cocktail (78420, Thermo Fisher Scientific). Once collected, the samples were rotated at 4°C for 30 min and centrifuged at 13,000 g for 10 min at 4°C. Lysates were blotted on NuPAGETM 4 to 12%, Bis-Tris. 1.0 mm Gel (NP0323BOX. ThermoFisher). Proteins from lysates were blotted using the following antibodies: NLRC3 antibody (ab77817, RRID:AB_2042467, Abcam), Phospho-TBK1/NAK (Ser172) Antibody (5483S, RRID: AB_10693472, Cell Signaling Technology), TBK1/NAK Antibody (3504S, RRID: AB_225566, Cell Signaling Technology), Phospho-STING (Ser365) Antibody (72971S, RRID: AB_2799831, Cell Signaling Technology), STING Antibody (13647S, RRID: AB_2732796, Cell Signaling Technology), phospho-IRF-3 (Ser396) Antibody (4947S, RRID: AB_823547, Cell Signaling Technology), IRF-3 Antibody (4302S, RRID: AB_1904036, Cell Signaling Technology), and anti-beta actin antibody (ab49900, RRID: AB_867494, Abcam). The secondary antibodies anti-rabbit IgG-HRP Antibody (ab97051, RRID: AB_10679369, Abcam) and anti-mouse IgG-HRP Antibody (ab97023, RRID: AB_10679675, Abcam) were used as needed. The dilutions for the primary antibodies were as follows: β -actin, 1:100,000; and 1:1000 for other antibodies. All antibodies were diluted in 5% skim milk. To assess the interaction between NLRC3 and STING, HA-NLRC3 and FLAG-STING plasmids were transfected into PCI-13, FADU, and UMSCC22A cells. Whole-cell lysates were harvested on ice in NP40 buffer (50 mM Tris-HCl pH 8.0, 150 mM NaCl, and 0.1% NP-40) supplemented with a protease inhibitor cocktail (11836170001, Roche) and Halt Phosphatase Inhibitor Cocktail (78420, Thermo Fisher Scientific). FLAG-STING and HA-NLRC3 proteins were pulled down by using the anti-FLAG M2 Affinity gel (A2220, Millipore Sigma) and Anti-HA Agarose (26181, Thermo Fisher Scientific). After three gently washes, immunoprecipitated protein complexes were resuspended in 1× LDS sample buffer, boiled at 95°C for 5 min, then were blotted using the following antibodies: anti-FLAG M2 Antibody (14793, RRID:AB_2572291, Cell Signaling Technology) and anti-HA-Tag Antibody (3724, RRID:AB_1549585, Cell Signaling Technology).

Histology, immunohistochemistry, and oil red O staining

After formalin fixation and paraffin embedding, specimens were sectioned, deparaffinized on a 58°C drying bench for 20 min, and then rehydrated. Retrieval buffer (Hk081-20k, Biogenex) was used for antigen unmasking and 0.3% hydrogen peroxide was used for quenching the endogenous peroxidase. Sections were blocked with 5% goat serum in PBS-T for 1 h and incubated with an anti-Acly antibody (LS-B13453, LSBio) or an anti-NIrc3 antibody (ab77817, RRID:AB_2042467, Abcam) at 4°C overnight. After washing twice in PBS-T buffer for 5 min each, the specimens were incubated with a secondary antibody (1:100 dilution) at room

temperature for 30 min. Then we used an ABC kit (PK-4001, Vectastain) for the addition of Avidin-Biotinylated HPR Complex. Sections were incubated with DAB (D4168-5SET, Sigma) for 3 min and stopped in water. For the Oil Red O staining, liver specimens were embedded in OTC and sectioned. After air-dry at room temperature, the slides were fixed in 10% Neutral Buffered Formalin. Then they were rinsed in water and dipped in 60% isopropanol (A426P-4, Fisher Scientific). The slides were placed in the Oil Red O – Isopropanol Solution (H-503-1B, Rowley Biochemical), washed twice, and then stained with Harris Hematoxylin (NC9520196, Fisher Scientific) for 15 s. The images were analyzed using ImageJ.

AlamarBlue assay

Empty vector control or shNIrc3-MOC2-E6/E7 cells were seeded at a density of 500 cells per well in 96-well microplates with a flat black bottom (3904, Corning). Every 24 h from day 1 to day 4, corresponding wells were supplemented with 10% alamarBlue (DAL1025, Invitrogen), and the plate was subsequently incubated at 37°C for 4 h. The fluorescence intensity (excitation 560, emission 590 nm) of these wells was measured using a Synergy H1 microplate reader (Agilent) and Gen5 program (version 2.09), and five replicates per group were examined simultaneously.

Quantitation of serum cholesterol levels

Serum cholesterol was measured using a luminescent plate assay (J3190, Promega) according to the manufacturer's instructions. Blood was collected from mice prior to euthanasia by submandibular bleeds and collected in Microvette 500 Serum Gel collection tubes (20.1344, Sarstedt). The luminescent intensity was measured using the Synergy H1 microplate reader (Agilent) and the Gen5 program (version 2.09).

Flow cytometry

Immune cells from tumors and spleens were purified. Tumors were excised from mice, weighed, and minced into pieces, followed by tissue dissociation and passage through a 70- μ m cell strainer to obtain a single-cell suspension. Spleens were processed by mechanical dissociation, followed by lysis of red blood cells with ACK lysing buffer (A10492-01, Gibco). Ficoll-Paque PLUS (17-1440-03, GE Healthcare Life Sciences) was added to the bottom of each tube containing single-cell suspensions in RPMI1640, followed by density-gradient centrifugation to purify immune cells. In general, approximately 1 × 10⁶ tumor-infiltrating lymphocytes were extracted from tumors post-Ficoll purification. Cells were subsequently stained for multi-fluorophore flow cytometric analysis with the following antibodies: anti-CD45 (clone 30-F11, BioLegend), anti-TCR β chain (clone H57-597, BioLegend), anti-TCR $\gamma\delta$ (clone GL3, BioLegend), anti-CD4 (clone RM4-5, BioLegend), anti-CD8 (clone 53-6.7, BioLegend), anti-IFN- γ (clone XMG1.2, BioLegend), anti-PD-1 (clone 29F.1A12, BioLegend), anti-CD11b (clone M1/70, BioLegend), and anti-Ly-6G (RB6-8C5, BioLegened). Cells were also stained for viability using Zombie Aqua (423101, BioLegend) diluted 1:1000 in PBS at 4°C for 30 min. Flow cytometric acquisition and initial compensation were conducted on a Beckman Coulter CytoFLEX and BioRad ZE5 Cell Analyzer. Approximately 0.5 × 10⁵ tumor-infiltrating lymphocytes were acquired per experiment. FlowJo version 10 software was used for compensation and data analysis.

MDSC functional assay

In vitro generation of MDSCs involved first harvesting bone marrow from lean and obese mice following the previously described protocol. Once cells were obtained in a single cell suspension, cells were incubated in MDSC differentiation media (RMPI-1640, 1% L-glutamine, 10% heat-inactivated fetal bovine serum, and 50uM β-mercaptoethanol 1% penicillin-streptomycin) containing 200 U/mL recombinant murine GM-CSF (315-03, PeproTech) for four days. Following this, the cells were treated with a combination of 0.1 μg/mL LPS (00-4976, Invitrogen) and 100 U/mL IFN-γ (575302, BioLegend) for 16 h to activate the MDSCs. Cells were stained using the following flow cytometric panel: Zombie Aqua (423101, BioLegend), anti-CD11b (clone M1/70, BioLegend), and anti-Ly-6G (RB6-8C5, BioLegened). FACS sorting on Beckman MoFlo Astrios Cell Sorter was used to isolate granulocytic MDSCS. Spleens from age-matched C57BL6/J mice were harvested, on the same day of MDSC sorting, to purify CD8⁺ T-cells for co-culture with MDSCs. First, spleens were collected in ice-cold PBS and then smeared against a 70-µM cell strainer to obtain a single-cell suspension. CD8+ T-cells were isolated using a murine EasySep CD8⁺ T cell isolation kit (19853, Stemcell Technologies) and then stained using 5 µM CFSE Violet Proliferation dye (C34554, Invitrogen) for 20 min in a 37°C incubator. MDSCs were dispended into wells containing labeled CD8⁺ T-cells and then stimulated with Dynabeads CD3/CD28 (11456D, Gibco) for four days to enable T cell expansion. Cells were then stained using the following panel: Zombie Aqua (423101, BioLegend), anti-CD8 (clone 53-6.7, BioLegend), and anti-CD11b (M1/70, BioLegened). CFSE dilution in CD8⁺ T-cells was analyzed by flow cytometry. MDSCS were also isolated from tumors grown in lean and obese mice. First, the tumors were harvested in RPMI1640 media, mashed, and processed using tumor dissociation media (RPMI1640, 1 mg/mL Collagenase I, 250 U/mL Collagenase IV, and 20 U/mL Dnase) for 30 min in 37°C water bath. Cells were stained using Zombie Aqua viability dye (423101, BioLegend) and the following antibodies: anti-CD45 (clone 30-F11, BioLegend), anti-CD11b (clone M1/70, Biolegend), and anti-Gr1 (clone RB6-8C5, Biolegend). Cells were sorted using Invitrogen Bigfoot Cell Sorter. At the same time, CD8⁺ T-cells were acquired from the spleens of lean mice and labeled with CFSE proliferation dye as previously described. MDSCs were dispensed into wells containing CFSE-labeled T-cells from and incubated with Dynabeads CD3/ CD28 for four days; after which, cells were stained using the previously described flow panel and analyzed for CFSE dilution using flow cytometry.

Single-cell immune profiling

Whole tumor lysate was treated with ACK Lysing Buffer (A1049201, ThermoFisher), then processed through an EasySep Dead Cell Removal (Annexin V) Kit (17899, STEMCELL Technologies). The cell suspension was submitted in 1× PBS +0.04% BSA for 10× Genomics 3'-single-cell processing and RNA-Seq at a depth of at least 30,000 reads per cell. We utilized the following criteria to select high-quality transcriptomes: (i) the qualified cells must have unique feature counts between 200 and 7,500; (ii) the mitochondrial reads must be fewer than 10%; (iii) the transcriptomes must have unique molecular identifiers counts over 500. We integrated 5,154 high-quality transcriptomes for downstream analyses. We utilized the sctransform tool to remove the library size effect and the mutual nearest neighbor algorithm to remove the batch effect for final integration. We selected the top 2,025 genes with the highest cell-to-cell variation as well as features to stabilize the immune population structure. The single-cell dataset is deposited to the NCBI Sequence Read Archive with a BioProject ID PRJNA756027.

QUANTIFICATION AND STATISTICAL ANALYSIS

Statistical analysis between two independent groups was made using unpaired, two-tailed Student's t-tests. Comparisons between more than two groups were made using two-way ANOVA with Šidák's multiple-comparisons post hoc analysis. Tumor burden between groups was compared using the generalized estimating equation model unless otherwise specified. Statistical significance is indicated in all figures according to the following scale: *p < 0.05; **p < 0.01; ***p < 0.001; and ****p < 0.0001. All graphs are presented as the mean \pm SEM. To test the differentially expressed genes between T-cells separated from the tumors in lean control mice and the tumors grown in obese mice, we employed the R-package "stats" and performed the non-parametric Wilcoxon test.
